(Uncertainty & noise)-free system

$$x(t) = X(t, t_0, x_0)$$

$$y(t) = h(t, x(t))$$

Uncertain and noisy system

$$x(t) = X(t, t_0, x_0, w_{t_0}^t)$$

$$y(t) = h(t, x(t)) + v(t)$$

Constraints

- $x(t) \in \mathbb{X}(t) \subset \mathbb{R}^n$
- $w(t) \in \mathbb{W}(t) \subset \mathbb{R}^{n_w}$ Uncertainties/Disturbances.
- $v(t) \in \mathbb{V}(t) \subset \mathbb{R}^{n_y}$ Measurement noise

Definitions and notation (2): Measurements-compatible configurations

Consider

- Time interval $[t - T, t]$
- Measurement profile y_{t-T}^t
- $(\xi, \mathbf{w}) \in \mathbb{X}(t - T) \times [\mathbb{R}^{n_w}]^{[t-T, t]}$

Consider

- Time interval $[t - T, t]$
- Measurement profile y_{t-T}^t
- $(\xi, \mathbf{w}) \in \mathbb{X}(t - T) \times [\mathbb{R}^{n_w}]^{[t-T, t]}$

(ξ, \mathbf{w}) is (y_{t-T}^t) -compatible

if for all $\sigma \in [t - T, t]$:

- 1 $w(\sigma) \in \mathbb{W}(\sigma)$,
- 2 $X(\sigma, t - T, \xi, \mathbf{w}) \in \mathbb{X}(\sigma)$,
- 3 $y_{t-T}^t(\sigma) - Y(\sigma, t - T, \xi, \mathbf{w}) \in \mathbb{V}(\sigma)$.

Notation

$$(\xi, \mathbf{w}) \in \mathbb{C}(t, y_{t-T}^t)$$

$(\xi, \mathbf{w}) \in \mathbb{C}(t, y_{t-T}^t)$ if the corresponding trajectory

- 1 meets the constraints
- 2 explains the measurements

The finite horizon observation problem

Choose a finite $T > 0$ and use at each t , the available information:

- ① System equations
- ② Past measurements y_{t-T}^t ,
- ③ Constraints and
- ④ *Some additional exogenous knowledge.*

in order to produce an estimation $\hat{x}(t)$ of the current state $x(t)$.

The finite horizon observation problem

Choose a finite $T > 0$ and use at each t , the available information:

- ① System equations
- ② Past measurements y_{t-T}^t ,
- ③ Constraints and
- ④ *Some additional exogenous knowledge.*

in order to produce an estimation $\hat{x}(t)$ of the current state $x(t)$.

Find $(\xi, \mathbf{w}) \longrightarrow \hat{x}(t) = X(t, t - T, \xi, \mathbf{w})$

The finite horizon observation problem

Choose a finite $T > 0$ and use at each t , the available information:

- ① System equations
- ② Past measurements y_{t-T}^t ,
- ③ Constraints and
- ④ *Some additional exogenous knowledge.*

in order to produce an estimation $\hat{x}(t)$ of the current state $x(t)$.

$$\text{Find } (\xi, \mathbf{w}) \longrightarrow \hat{x}(t) = X(t, t - T, \xi, \mathbf{w})$$

The set of candidate estimates $\hat{x}(t)$:

$$\Omega_t = \left\{ X(t, t - T, \xi, \mathbf{w}) \mid (\xi, \mathbf{w}) \in \mathbb{C}(t, y_{t-T}^t) \right\}.$$

The need for additional knowledge

$$\Omega_t = \left\{ X(t, t - T, \xi, \mathbf{w}) \mid (\xi, \mathbf{w}) \in \mathbb{C}(t, y_{t-T}^t) \right\}.$$

- Either $\Omega_t = \{x(t)\}$, for instance because
 - $\mathbb{W} = \{0\}$, $\mathbb{V} = \{0\}$ and
 - The system has no indistinguishable states

$$\int_{t-T}^t \|Y(\sigma, t - T, x^{(1)}) - Y(\sigma, t - T, x^{(2)})\|^2 d\sigma \geq \alpha(\|x^{(1)} - x^{(2)}\|)$$

for all $t \geq 0$ and all $(x^{(1)}, x^{(2)}) \in \mathbb{X}(t - T) \times \mathbb{X}(t - T)$.

The need for additional knowledge

$$\Omega_t = \left\{ X(t, t - T, \xi, \mathbf{w}) \mid (\xi, \mathbf{w}) \in \mathbb{C}(t, y_{t-T}^t) \right\}.$$

- Or $\Omega_t \neq \{x(t)\}$, and a *selection* must be made by solving

$$P(t) : \min_{(\xi, \mathbf{w}) \in \Omega_t} \Phi(\xi) + J(t, \xi, \mathbf{w}) \rightarrow (\hat{\xi}(t), \hat{\mathbf{w}}(t))$$

- Estimation: $\hat{x}(t) = X(t, t - T, \hat{\xi}(t), \hat{\mathbf{w}}(t))$
- $\Phi(\xi)$ is the cost to go
(summary of the past measurement related information)
- In the sequel $\Phi(\xi) + J(t, \xi, \mathbf{w})$ is shortly denoted by $J(t, \xi, \mathbf{w})$

Temporal Parametrization (1)

Outline

Problem
Statement

Example 1

Singularity
Crossing

Example 2

Example 3

Real-Time
Issues

Differential
Form

Discrete
Form

Example 4

ANR-CLPP

Example 5

Conclusion

Further
readings

$$\text{Solve } P(t) \quad : \quad \min_{(\xi, \mathbf{w}) \in \mathbb{C}(t)} J(t, \xi, \mathbf{w})$$

In many textbooks, the following parametrization is suggested for \mathbf{w} :

$$\rho_w := \{\mathbf{w}(kT)\}_{k=k_0}^{k_0+N-1} \in \mathbb{W}(k_0) \times \cdots \times \mathbb{W}(k_0 + N - 1) \subset \mathbb{R}^{n_w \cdot N}$$

- Decision variable (ξ, ρ_w) of **dimension** $n + N \cdot n_w$
- Too rich spectral content *increasing* uselessly Ω_t
- **High sensitivity** to the knowledge of $\mathbb{W}(\cdot)$.

Unrealistically too many possible interpretations of the measurements

Temporal parametrization (2)

$$\text{Solve } P(t) : \min_{(\xi, \mathbf{w}) \in \mathbb{C}(t)} J(t, \xi, \mathbf{w})$$

Use a reduced dimensional parametrization

$$\mathbf{w}(t) = \mathcal{W}(t, \mathbf{p}_w) \quad ; \quad \mathbf{p}_w \in \mathbb{P}.$$

$$\text{Solve } P(t) : \min_{(\xi, \mathbf{p}_w) \in \mathbb{C}(t)} J(t, \xi, \mathcal{W}(\cdot, \mathbf{p}_w)) =: J(t, \xi, \mathbf{p}_w) \rightarrow (\hat{\xi}(t), \hat{\mathbf{p}}_w(t))$$

$$\hat{\mathbf{x}}(t) = \mathbf{X}(t, t - T, \hat{\xi}(t), \mathcal{W}(\cdot, \hat{\mathbf{p}}_w(t)))$$

- $\bar{\mathbf{x}} := (\mathbf{x}^T, \mathbf{p}_w^T)^T \in \mathbb{R}^n \times \mathbb{R}^{n_p}$ **New uncertainty-free extended state estimation problem.**
- $\dot{\mathbf{p}}_w = 0$

Analytic observers

$$\text{(System)} \quad \dot{x} = f(x) ; y = h(x)$$

$$\text{(Observ)} \quad \dot{\hat{x}} = f(\hat{x}) + K(\hat{x}, y)$$

Try to show asymptotic convergence of $e = x - \hat{x}$ governed by

$$\dot{x} = f(x)$$

$$\dot{e} = f(x) - f(x - e) - K(x - e, h(x))$$

Very Hard Task

- Need for structural properties
- Coordinate transformation
- Constructive assumptions
- Observability \neq Existence of observer

Analytic observers

(System) $\dot{x} = f(x) ; y = h(x)$

(Observ) $\dot{\hat{x}} = f(\hat{x}) + K(\hat{x}, y)$

Try to show asymptotic convergence of $e = x - \hat{x}$ governed by

$$\dot{x} = f(x)$$

$$\dot{e} = f(x) - f(x - e) - K(x - e, h(x))$$

Very Hard Task

- Need for structural properties
- Coordinate transformation
- Constructive assumptions
- Observability \neq Existence of observer

Optimization based observers

Rely on the implication

$$\{J(t, \xi) \rightarrow 0\} \Rightarrow \underbrace{\{X(t, t - T, \xi) \rightarrow x(t)\}}_{\hat{x}(t)}$$

- + No need to study the dynamic of e
- + No need for structural assumptions
- + Observability \Leftrightarrow Observer
- + Handling constraints on the state

Potential problems

- Global convergence ?
- Computation time ?

Example: State estimation of terpolymerization reactors

Example 3: Back to ter-polymerization (Simulation results)

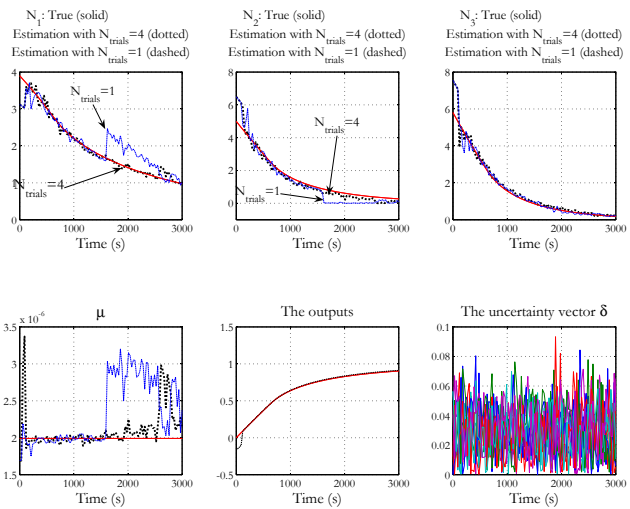

Figure: Comparison between the observer behavior when $n_\phi = 1$ and $n_\phi = 4$ under the scenario depicted on figure 2. Note how the singularity cross mechanism enables to avoid drops in the estimation quality when the observer encounters a singular situation. This scenario uses a tolerance $\varepsilon = 10^{-8}$ for the optimization subroutine.

Example 3: Back to ter-polymerization (Experimental results: $n_\phi = 10$)

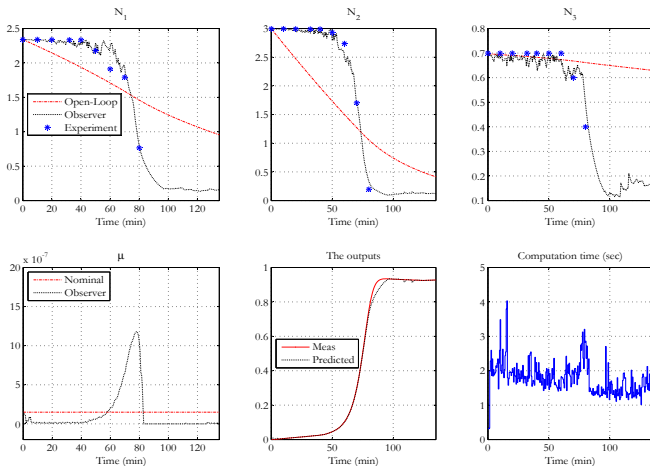

Figure: *Experimental validation with $n_\phi = 10$ and tolerance threshold $\varepsilon = 10^{-3}$. The same scenario is depicted on figure 6 where $n_\phi = 1$ is used. The computation time is given in seconds.*

Example 3: Back to ter-polymerization (Experimental results: $n_\phi = 1$)

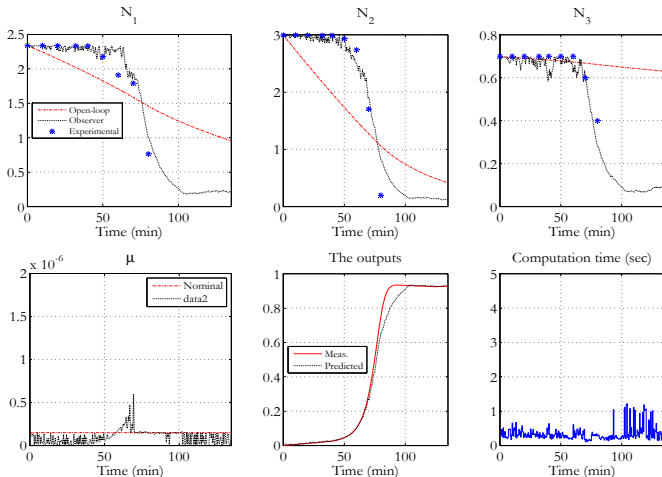

Figure: Experimental validation with $n_\phi = 1$ and tolerance threshold $\varepsilon = 10^{-3}$. The same scenario is depicted on figure 5 where $n_\phi = 10$ is used. The computation time is given in seconds.

Discussion

- The scheme holds regardless the optimizer \mathcal{S}
 - Gradient-based iteration
 - SQP
 - multiple shooting
 - non smooth (simplex, powell's, etc.)
- Easily usable in a parallel architecture
[parallel $(z^{(0)}, J_i)$ path-solvers exploration]
- \neq a multiple initial guess scheme
[It's the cost function that changes not the present solution]

Discussion

- The scheme holds regardless the optimizer \mathcal{S}
 - Gradient-based iteration
 - SQP
 - multiple shooting
 - non smooth (simplex, powell's, etc.)
- Easily usable in a parallel architecture
[parallel $(z^{(0)}, J_i)$ path-solvers exploration]
- \neq a multiple initial guess scheme
[It's the cost function that changes not the present solution]
- Price: Loose optimality that is *loosely defined*

Analytic observers

$$\text{(System)} \quad \dot{x} = f(x) ; y = h(x)$$

$$\text{(Observ)} \quad \dot{\hat{x}} = f(\hat{x}) + K(\hat{x}, y)$$

Try to show asymptotic convergence of $e = x - \hat{x}$ governed by

$$\dot{x} = f(x)$$

$$\dot{e} = f(x) - f(x - e) - K(x - e, h(x))$$

Very Hard Task

- Need for structural properties
- Coordinate transformation
- Constructive assumptions
- Observability \neq Existence of observer

Optimization based observers

Rely on the implication

$$\{J(t, \xi) \rightarrow 0\} \Rightarrow \underbrace{\{X(t, t - T, \xi) \rightarrow x(t)\}}_{\hat{x}(t)}$$

- + No need to study the dynamic of e
- + No need for structural assumptions
- + Observability \Leftrightarrow Observer
- + Handling constraints on the state

Potential problems

- Global convergence ?
- Computation time ?

Example 5

Conclusion

Further
readings

For system of the form $\dot{x} = f(t, x)$:

$$\begin{aligned}\dot{\xi}(t) &= f(t - T, \xi(t)) + c(t, \xi(t)) \\ \hat{x}(t) &= X(t, t - T, \xi(t))\end{aligned}$$

Uniform Global Regularity Assumption

There is a K-function $\Upsilon : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ such that the following inequality holds:

$$\|J_{\xi}(t, \xi)\|^2 \geq \Upsilon(J(t, \xi))$$

for all (t, ξ)

- The correction term

$$c(t, \xi) := \gamma \left[\frac{J_{\xi}^T(t, \xi)}{\|J_{\xi}\|^2 + \varepsilon} \right] \left[-|\Delta_{t-T}^t(\epsilon_y(\cdot, \xi))| - [1 + \phi(t, \xi)] \sqrt{J} \right]$$

- **Post-Stabilization technique** \rightarrow improve (Sampling period)/Precision ratio
- [M. Alamir *Optimization Based Nonlinear Observer Revisited ... Int. J. of Control* 1999]

Convergence result

If the following conditions hold:

- ① The maps are continuously differentiable
- ② The system is uniformly observable
- ③ The uniform regularity assumption is satisfied

then for any a priori fixed desired precision $\eta > 0$ on the state estimation error, there is a sufficiently high ratio γ/ε such that the dynamic system given by:

$$\begin{aligned}\dot{\xi}(t) &= f(t - T, \xi(t)) + c(t, \xi(t)) \\ \hat{x}(t) &= X(t, t - T, \xi(t))\end{aligned}$$

where the correction term $c(t, \xi)$ is given by:

$$c(t, J) := \gamma \left[\frac{J_{\xi}^T(t, \xi(t))}{\|J_{\xi}\|^2 + \varepsilon} \right] \left[-|\Delta_{t-T}^t(\epsilon_y(\cdot, \xi(t)))| - [1 + \phi(t, \xi(t))] \sqrt{J} \right]$$

leads to an estimation error that is asymptotically lower than η .

The Post Stabilization Technique

$$\begin{aligned}\dot{\xi}(t) &= f_c(t, \xi(t), J_\xi(t)) \\ \hat{x}(t) &= X(t, t - T, \xi(t)) \\ J(t, \xi(t)) &= 0 \quad (\text{Ideally})\end{aligned}$$

$$\begin{aligned}\dot{\xi}(t) &= f_c(t, \xi(t), J_\xi(t)) \\ \hat{x}(t) &= X(t, t - T, \xi(t)) \\ J(t, \xi(t)) &= 0 \quad (\text{Ideally})\end{aligned}$$

Good News: Ideally, DAE's with invariant submanifold

→ There are techniques (Ascher, Num. Alg. 1997) to accurately integrate with lower order methods

- ① Integrate over $[t_k, t_{k+1}]$ starting from the initial condition $(t_k, \xi(t_k))$

$$\dot{\xi}(t) = f_c(t, \xi(t), J_{\xi}(t_k)) \quad ; \quad t \in [t_k, t_{k+1}]$$

to obtain $\tilde{\xi}(t_{k+1})$

- 1 Integrate over $[t_k, t_{k+1}]$ starting from the initial condition $(t_k, \xi(t_k))$

$$\dot{\xi}(t) = f_c(t, \xi(t), J_\xi(t_k)) \quad ; \quad t \in [t_k, t_{k+1}]$$

to obtain $\tilde{\xi}(t_{k+1})$

- 2 Correct the *rough* approximation $\tilde{\xi}(t_{k+1})$ by projection

$$\xi(t_{k+1}) = \tilde{\xi}(t_{k+1}) - \frac{J_\xi(t_{k+1}, \tilde{\xi}(t_{k+1}))}{\|J_\xi(t_{k+1}, \tilde{\xi}(t_{k+1}))\|^2 + \nu} \cdot J(t_{k+1}, \tilde{\xi}(t_{k+1}))$$

to obtain the update $\xi(t_{k+1})$

Convergence analysis

Regardless the order of the integration scheme, one has

$$\lim_{k \rightarrow \infty} J(\xi(t_k)) = O(\tau_s^4)$$

- 1 Integrate over $[t_k, t_{k+1}]$ starting from the initial condition $(t_k, \xi(t_k))$

$$\dot{\xi}(t) = f_c(t, \xi(t), J_\xi(t_k)) \quad ; \quad t \in [t_k, t_{k+1}]$$

to obtain $\tilde{\xi}(t_{k+1})$

- 2 Correct the *rough* approximation $\tilde{\xi}(t_{k+1})$ by projection

$$\xi(t_{k+1}) = \tilde{\xi}(t_{k+1}) - \frac{J_\xi(t_{k+1}, \tilde{\xi}(t_{k+1}))}{\|J_\xi(t_{k+1}, \tilde{\xi}(t_{k+1}))\|^2 + \nu} \cdot J(t_{k+1}, \tilde{\xi}(t_{k+1}))$$

to obtain the update $\xi(t_{k+1})$

Example 4

ANR-CLPP

Example 5

Conclusion

Further
readings

During the interval $[t_k, t_{k+1}]$, perform n iterations of some iterative process S :

$$\tilde{\xi}(t_k) = S^{(n)}\left(t_k, \xi(t_k), y_{t_k-T}^{t_k}\right)$$

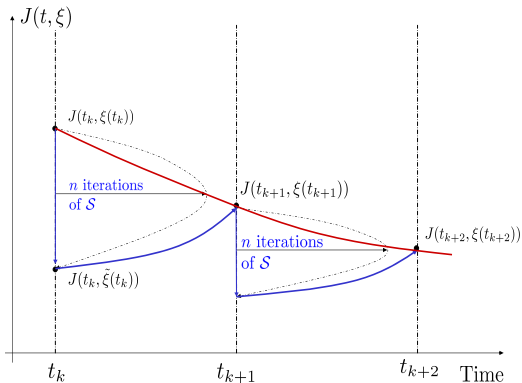

Using $\tilde{\xi}(t_k)$, update the value of $\xi(t_{k+1})$ according to

$$\xi(t_{k+1}) = X(t_{k+1} - T, t_k - T, \tilde{\xi}(t_k))$$

Two opposite processes

The updating mechanism involves **two opposite effects** on $J(t_k, \xi(t_k))$:

- 1 A **decreasing effect** from the n -iterations of the optimization process
- 2 An **increasing effect** from the open loop prediction over $\tau_u = N\tau_a$.

Assumption: Efficiency of the optimizer

The iterative process \mathcal{S} is **efficient** in the sense that there exists some efficiency map $\alpha_{eff} : \mathbb{N} \rightarrow [0, 1[$ such that for all t and ξ , one has:

$$J(t, \mathcal{S}^{(n)}(t, \xi, y_{t-T}^t)) \leq \alpha_{eff}(n) \cdot J(t, \xi)$$

where $\alpha(\cdot)$ is a decreasing function such that $\alpha(0) = 1$.

Assumption: Open-loop behavior of the cost function

When using open-loop prediction, the only inequality one can guarantee is given by:

$$J(t + \tau, X(t + \tau - T, t - T, \xi)) \leq [J(t, \xi)] \cdot \vartheta(\tau) \quad (1)$$

Moving-Horizon Observers with Distributed Optimization

A rather qualitative result

Under the assumptions above, the convergence of the distributed in time optimization based observer is guaranteed provided that the following inequality holds:

$$\varpi(N_u) := \alpha_{\text{eff}} \left(E \left(\frac{N_u \tau_a}{\tau_{\text{iter}}} \right) \right) \cdot \vartheta(N_u \tau_a) < 1 \quad (2)$$

Moreover, the *convergence time* is given by:

$$t_r(N_u) \approx \left[\frac{3N_u}{|\log(\varpi(N_u))|} \right] \cdot \tau_a \quad (3)$$

where

- ✓ τ_a is the measurement acquisition period
- ✓ $N_u \tau_a$ is the updating period
- ✓ τ_{iter} is the time necessary to perform one iteration of the process \mathcal{S}

Take the following example for illustration

$$\alpha_{eff}(n) = \frac{D}{n^d + D} \quad ; \quad \vartheta(\tau) = \exp(\beta \cdot \tau)$$

Note that:

- $d \nearrow$ increases the efficiency
- $D \nearrow$ decreases the efficiency
- $\alpha_{eff}(0) = 1$
- $\beta \nearrow$ assumes high model discrepancy

Take the following example for illustration

$$\alpha_{\text{eff}}(n) = \frac{D}{n^d + D} \quad ; \quad \vartheta(\tau) = \exp(\beta \cdot \tau)$$

Note that:

- $d \nearrow$ increases the efficiency
- $D \nearrow$ decreases the efficiency
- $\alpha_{\text{eff}}(0) = 1$
- $\beta \nearrow$ assumes high model discrepancy

Example 5

Conclusion

Further
readings

Figure: Evolutions of the stability indicator $\varpi(N_u)$ and the settling time $t_r(N_u)$ vs the number of iterations N_u used to update the state estimation. $D = 3$, $d = 1$, $\beta \cdot \tau_a = 0.3$ and $\tau_a/\tau_{iter} = 5$. Under these conditions, **stability cannot be guaranteed when more that 9 iterations are used**. The **optimal choice** (in term of settling time) is the one where only **one iteration** is used to perform the updating.

Example 5

Conclusion

Further
readings

Figure: Evolutions of the stability indicator $\varpi(N_u)$ and the settling time $t_r(N_u)$ vs the number of iterations N_u used to update the state estimation. $D = 50$, $d = 2$, $\beta \cdot \tau_a = 0.05$ and $\tau_a/\tau_{iter} = 5$. Under these conditions, while **stability seems guaranteed regardless the number of iterations** used to perform the updating, the use of **3 iterations** gives the best result in term of settling time.

Consider the following state/parameter estimation problem:

$$\dot{x}_1 = x_2$$

$$\dot{x}_2 = -px_1 + 2(1 - x_1^2)x_2$$

$$y = x_1$$

with $p \in [5, 10]$
